On post-stratification weighting of the sample

To secure representativeness, the survey material is weighted by the data collection company. With a known distribution of the population on three dimensions sex, age, and geography, survey responses are weighted so that the surveys are nationally/state representative.¹ The weights are represented by a single variable in the datasets named "weight" and the figures vary for each respondent to signify the weight applied to that individual respondent. When the number in the column "weight" equals 1 it indicates that we have an equal distribution in the survey sample as in the distribution in the population. Thus, figures close to 1 indicate approximately equal distribution to that of the population.

¹ In Norway, the weights are applied within each of the five counties for as an additional measure to secure representativeness.
